Abstract

In a motor-driven dental care device comprising an exchangeable cleaning head (brush or polishing attachment) the cleaning head executes arched reversing movements, overlapping the teeth, between the palate and the lips. It is designed as a dish spanning the teeth like a vault, the dish being located so as to be elastically pliable in a driven running tray and fitted with soft brushes in the edge zones. The cleaning head comprises a closely adjacent group of segments distributed over the entire mandibular arch and simultaneously driven by a flexible shaft.
